

REVISION OF THE SUBGENUS *OENOSCHOENGASTIA*,
WOMERSLEY AND KOHLS, 1947
(ACARINA : TROMBICULIDAE)¹

BY

P. H. VERCAMMEN-GRANDJEAN and S. G. WATKINS²

The genus *Oenoschoengastia* was raised in 1947 (9) to accomodate the unique species *O. cana*, exception being made for the peculiar aspect of the cheliceral blade. This species definitely belongs, in all its other characters, to the genus *Schoengastia*, and therefore, *Oenoschoengastia* was considered by V.-G., 1960 (5) to be a subgenus of the former.

We were very fortunately able to study the holotype and seventeen paratypes of *O. cana* thanks to the kindness of Dr. Peter AITKEN, assistant curator of insects, S. Australien Museum, ADELAIDE, to whom we are grateful for the loan.

Schoengastia (Oenoschoengastia) cana (Womersley and Kohls, 1947).

- = *Oenoschoengastia cana* WOM. and KOHLS, 1947, WOM. 1952, BAKER and WHARTON, 1952, WHARTON and FULLER, 1952, GUNTHER, 1952, AUDY, 1954, RADFORD, 1954, WOM. and AUDY, 1957.
- = *Schoengastia (Oenoschoengastia) cana*, V.-G., 1960.

A. — *Diagnosis* : *Schoengastia* possessing a cheliceral blade with multidentate apex and showing no definite tricuspid cap (fig. 3). The identification formula (5) is that of an authentic *Schoengastia* : 7 B.S — N — 3111.100. Scutum as in *Schoengastia* s. str., the posterior two-thirds covered by pleated ectostracum ; typical bulbose sensillae covered with inconspicuous and tiny spicules ; AM short ; ALs much longer than PLs, both of which are covered with numerous long, slender barbs. Subterminala and parasubterminala of tarsus 1 present, as are pretarsala 1 and 2.

B. — *Host and Parasitope* : *Talegallus* sp. ? ("bush turkey") ; from the mound.

1. This study was supported by PHS Research Grant AI-03793-03 from the National Institute of Allergy and Infectious Diseases, U. S. Public Health Service.

2. Research Parasitologist (senior) and Laboratory Technician (junior) : The George Williams HOOPER Foundation, University of California Medical Center, San Francisco 22, California, U. S. A.

C. — Locality and Date : Dobadura, New Guinea, 18 May, 1944 (coll. G. M. K., No. 325).

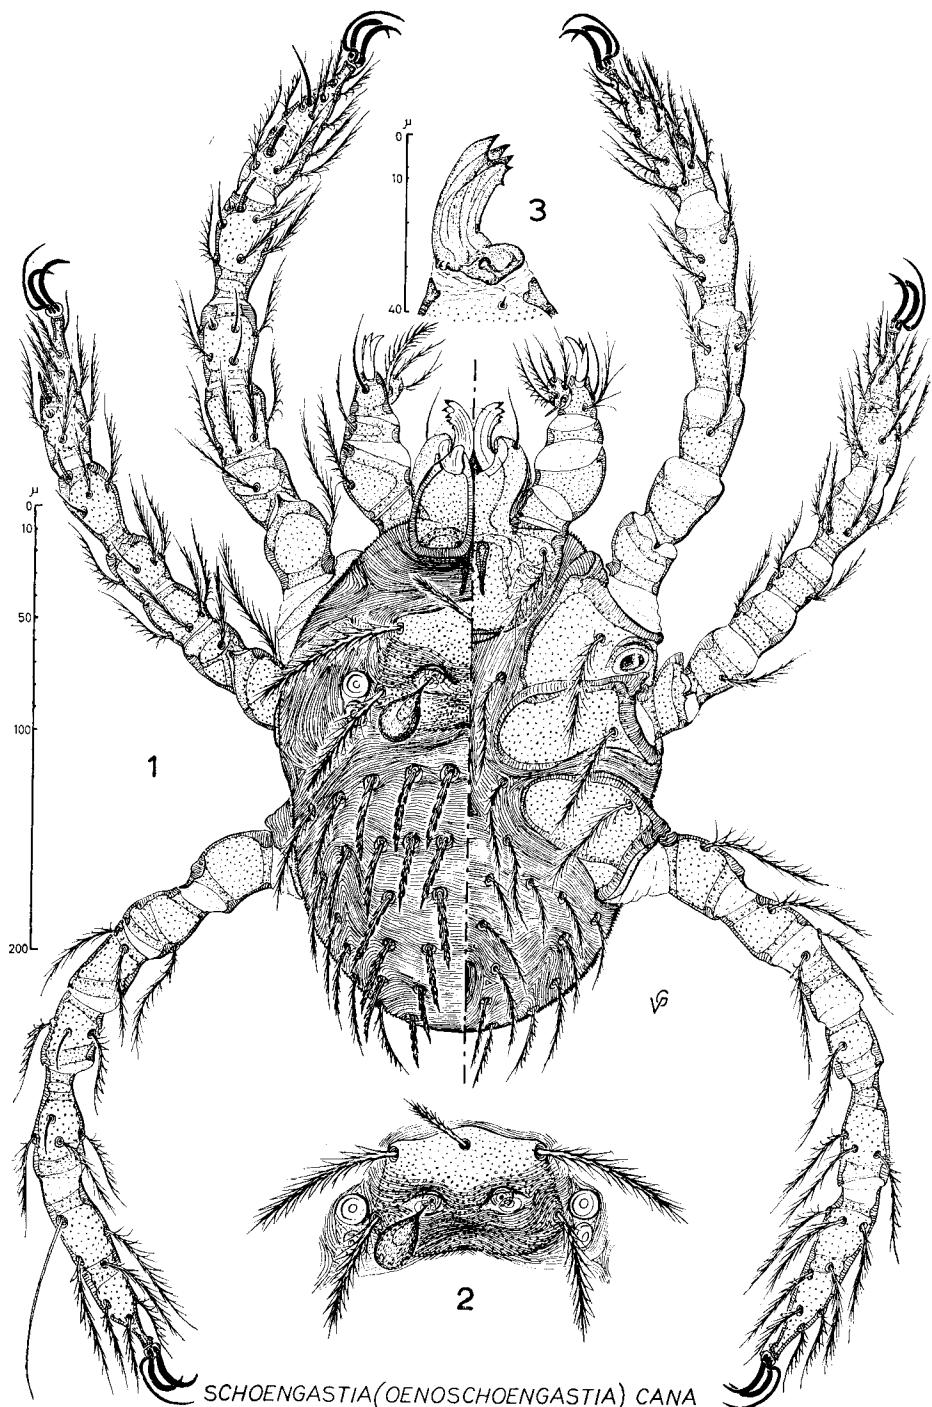

D. — Description :

1) Measurements : of the holotype and seventeen paratypes, with the means and observed range (in micra) :

N. B. For the sensillae, we established the following detailed mean measurements : bulb length 24 μ , bulb diameter 17 μ , peduncle 13 μ .

SCHOENGASTIA (*OENOSCHOENGASTIA*) CANA

WOMERSLEY & KOHLS, 1947.

2) *Scutum* : (fig. 2) Subtrapezoidal, anterior margin convex above the AM base, posterior margin rounded and slightly concave at the middle ; scutal surface abundantly and conspicuously punctate, the posterior two-thirds covered by pleated ectostracum. Sensillae globose, with a short peduncle, bulb covered with numerous inconspicuous, tiny spicules, sensillary base line slightly forward of the PL's. AM short, resembling a barley ear ; ALs and PLs longer and provided with numerous long, slender barbs : $AL > PL > AM$. On each side of the scutum is a pair of eyes on a sclerotized plate, the anterior ocellus the larger and situated on the sensillary base line.

3) *Idiosoma* : (fig. 1) All specimens having been collected unattached in a mound, the larvae are unengorged and we are able to provide the mean measurements for body dimensions of the living mite, corrected by calculation to allow for compression in mounting : body length = 170μ , body width = 115μ , body height = 115μ . The longitudinal ectostracial pleats observable on the propodosoma and opisthosoma, but not on the metapodosoma, allow us to assume that the engorged larva will develop the eight-shaped configuration typical to most trombiculid mites. A very peculiar feature is present in the body setation : mid-dorsal setae stout and shorter (38μ) covered with few enlarged barbs, in contrast to the slender and longer (46μ) dorso-lateral setae, covered with long, ordinary barbs.

Dorsal formula : $fD = 2H + 8.10.6.6.4 = 42$ dorsal setae.

Ventral formula : $fV = 8.4.4.4.2 = 22$ ventral setae.

$NDV = 42 + 22 = 64$ body setae. Uropore between fourth and fifth rows of ventral setae.

4) *Legs* : (fig. 1) These are relatively long, and $I\phi = 950$ shows a rather large species. Segmentation formula : $fsp = 7.7.7$

Coxal formula : $fCx = 1.1.1$ (all plumose setae).

Sternal formula : $fSt = 2.2.2$ (similar to coxals). Subterminala and para-subterminala present on tarsus 1, as are pretarsala on 1 and 2. Genuala and tibiala 3 as follows : $ga = 3$ (+ famulus), $gm = 1$, $gp = 1$ and $tp = 1$.

Tarsal bar formula : $fBT = 2b - 2b - 2b$. Long mastitarsala 3 (76μ).

5) *Gnathosome* : (figs. 1 & 3) Chelobase robust, cheliceral blade stout, with multidentate apex (no apparent tricuspid cap) (fig. 3). Galeal setae nude (a constant character in all *Schoengastia*).

Palpal formula : $fP\phi = (B) - (N') - (N).N.B.G_3 - E.B.B.B.S.(B).(B)$. and $fT = 7B.S$. Palpo-tibial claw stout and trifurcate. Gnathobase abundantly punctate (like the coxae), and provided with two plumose setae.
