REVISION OF THE GENERA: ELTONELLA AUDY, 1956
AND MICROTROMBICULA EWING, 1950,
WITH DESCRIPTIONS OF FIFTY NEW SPECIES
AND TRANSFERAL OF SUBGENUS CHIROPTELLA
TO GENUS LEPTOTROMBIDIUM (ACARINA, TROMBICULIDAE)

BY

P. H. VERCAMMEN-GRANDJEAN 2.

When one considers the whole range of trombiculid mites, the two genera Eltonella and Microtrombicula are found to be two very homogeneous groups, closely related and involving more than 100 species, and subspecies.

The subgenus Microtrombicula (in the genus Eutrombicula) was created by Ewing, 1950 (32) to accommodate the single species Microthrombidium minutissimum Oudemans, 1910 (55), and 1912 (56). Fuller in 1952 (36') redescribed Trombicula minutissimum without mentioning Ewing's action. He remarked that: "It is not related to other described species and it probably merits a genus of its own. For the present, however, it is placed provisionally in Trombicula sens. lat.". Wharton and Fuller, 1952 (82) placed this species in their subgenus Eutrombicula (genus Trombicula), commenting that the species may represent a new genus of the family. Meanwhile a wide range of species was being studied in the Congo and Malaya, and the present writer and Audy (1954) (8), independently identified a number of other trombiculids congeneric with T. minutissimum in 1957. Audy and Vercammen-Grandjean decided to resurrect the subgenus Microtrombicula (genus Trombicula) in an interim note which was prepared to support the arrangement of trombiculids in the checklist of Ethiopian Trombiculids contained in the monograph of Zumpt, 1961 (16). Unfortunately from the point of trombiculid taxonomy Zumpt's checklist came somewhat prematurely, the preparation of the trombiculid section coinciding with the preparation of the tentative scheme of classification or "essai" of Vercammen-Grandjean, 1960 (75). This accounts for several inconsistencies between the trombiculid

1. This investigation was supported by U. S. Public Health research grant E-3793 from the National Institute of Allergy and Infectious Disease, National Institutes of Health.
2. Research Parasitologist, G. W. Hooper Foundation, University of California Medical Center, San Francisco 22, California, U. S. A.

checklist and the scheme of classification which were published almost simultane­
ously.

*Eltonella* was raised as a subgenus of *Eutrombicula* Ewing by *Audy, 1956* (II) to accomodate three species: *T. frittsi* Wharton and two new species, *E. (E.) eltoni* and *E. (E.) tweedei, eltoni* having a nymph with paracristal eyes (see Pl. At). At about this time, *Audy* and *Vercammen-Grandjean* decided to erect a new sub­
genus of *Eutrombicula* to accomodate what *Audy* has been calling the "*lawrencei­
group*". This was done (subgenus *Squamicola*) in a paper prepared in undue haste in order to support *Zumpt*’s monograph: *Audy and Vercammen-Grandjean, 1961* (17), and to fit in with the publication date of that work. As it happened, *Audy* had not recognized the closeness of the identity of most of the species in *Squamicola* to *Eltonella* itself (i.e. their separation in another subgenus was unjustified), while *Vercammen-Grandjean* was still establishing his system of classification. It was too late to alter both the paper raising *Squamicola* and the arrangement in *Zumpt*’s monograph. Accordingly we should here recognize that:

1) *Squamicola* Audy and Vercammen-Grandjean, 1961, is a synonym of *Eltonella* Audy, 1956.

2) *Eltonella* is sufficiently distinct from *Eutrombicula sensu stricto* to be regarded as a genus, not a subgenus. *Vercammen-Grandjean, 1960* (75) divided the genus *Eltonella* into 4 subgenera.

The subgenus *Chiroptella* V.-G., 1960 was erected for a group of four species of which two had been seen and studied by the reviser (*insolli* and *revelae*) but unfortunately only one specimen of each species, and these specimens in poor condition. For the two other species (*piercei* and *bandupi*) not available, the identification had to be based on the original descriptions. Those circumstances lead to mistakes and, for instance, the palpapotarsal gross formula, *fT*, stated as 6B was actually 7B.

Thanks to Mr. M. Nadchatram (Kuala Lumpur), who helped efficiently to clarify the situation, the following can be stated:

1) The subgenus *Chiroptella* is placed under the genus *Leptotrombidium*.

2) Replacing *Chiroptella*, a new subgenus, *Traubiella*, is erected under the genus *Eltonella*, with the single species *multisternalae* as type,

3) *Chiroptella* (7B), *Traubiella* (6B) and *Sasatrombicula* (5B) (= *Hoffmanniella*) having in common the double genualae on leg 3, constitute a chain of very close bat chigger genera,

4) The genus *Chiroptella* is an important link, on one side between *Eltonella* and *Leptotrombidium*, on another side between *Myotrombicula* and *Leptotrombis­
dium*. 
I. — GENERAL TAXONOMIC CONSIDERATIONS

A. — Larvae.

I — Classification.

The three genera *Eutrombicula*, *Eltonella* and *Microtrombicula* are related in the general morphology of the larvae and particularly in the peculiar shape of the scuta which have more or less pronounced anterolateral "shoulders". *Eutrombicula* is readily separated from the other two genera by the palpotarsal setae, the gross formulae (fT) being *Eutrombicula* fT = 7B.S; *Eltonella* and *Microtrombicula* fT = 6B. On the other hand, while the palpal claws of *Eltonella* are 3-pronged, those of *Eutrombicula* and *Microtrombicula* are always 2-pronged.

I. Genus *Eltonella* Audy, 1956 (11).

*Diagnosis*: Trombiculini possessing a punctate scutum having anterior "shoulders" with a peculiar backward position of the two antero-lateral setae; palpotarsal gross formula, fT = 6B; palpal claws three-pronged; the two galeal setae are nude.

*Type species*: *Eutrombicula (Eltonella) eltoni* Audy, 1956 (11).

The genus *Eltonella* is here divided into four subgenera, of which *Eltonella s. str* is the most numerous: 37 species.

A — Subgenus *Traubiella* nov. 1.

*Diagnosis*: *Eltonella* with a typical scutum, sensillae branched on the distal half; eyes present; three genualae on leg 1, two on leg 3, no mastitarsala. Bat parasites.

*Type species*: *Eutrombicula (Chiroptella) multisternalae* V.-G., 1963 (76), comb. nov.

B — Subgenus *Coecicula* V.-G., 1960 (75).

*Diagnosis*: *Eltonella* possessing a typical scutum, pentagonal in shape, with two trifurcate sensillae; no eyes (blind species, reason for the name "Coecicula"); only one genuala on third leg; no mastitarsala 3.

*Type species*: *Trombicula mastomyia* Radford, 1942 (59).

1. Named after Dr. R. Traub; this following the suggestion of Mr. M. Nadchatram to whom I want to express here my deepest thanks for his friendly and generous intervention.
Subgenus Eltonella, Audy, 1956 (II).

Diagnosis: Eltonella having a scutum roughly pentagonal and sensillae with numerous branches; only one genuala on leg 3; paired eyes always present; one mastitarsala on leg 3.

Type species: Eutrombicula (Eltonella) eltoni Audy, 1956 (II).

Subgenus Marcandrea V.-G., 1960 (74).

Diagnosis: Eltonella having a scutum roughly trapezoidal in shape, with branched sensillae; no eyes (blind species); two genualae on leg 3; a fairly long tarsala 1 (striated spur or solenidion); no mastitarsala 3.

Type species: Microtrombicula (Marcandrea) fromonti V.-G., 1960 (74).

Genus Microtrombicula Ewing, 1950 (33).

Diagnosis: Trombiculini having a pentagonal shaped scutum with anterior "shoulders" and backwared antero-lateral setae; its sensillae either branched or flagelliform; palpotarsal gross formula: \( fT = 6B \), palpal claws two-pronged; always oculate and provided with one mastitarsala 3 and a single genuala 3.

Type species: Microthrombidium minutissimum Oudemans, 1910 (55).

The genus Microtrombicula is divided into two subgenera, Microtrombicula s. str. being the greater in number. The subgenus Scapuscutala is somewhat less homogenous.

Subgenus Microtrombicula Ewing, 1960 (33).

Diagnosis: Microtrombicula having a peculiar subpentagonal scutum, rather small, verruco- or reticulo-punctate, usually bearing bifurcate or flagelliform sensillae; two galeal setae always bare.

Type species: Microthrombidium minutissimum Oudemans, 1910 (55).

Subgenus Scapuscutala V.-G., 1960 (75).

Diagnosis: Microtrombicula having a punctate scutum, with branched sensillae.

Type species: Trombicula crossleyi Loomis, 1954 (48).

Value of Some Taxonomical Characters.

In each subgenus, certain peculiar secondary characters lead to a last tentative species grouping. For instance, Eltonella sg. is split into three groups:
r) gr. eltoni: with a scutum possessing a pointed posterior edge,

2) gr. rossi: with a rounded postero-scotal edge,

3) gr. gerrhosauri: an ecological grouping, closely related to some species belonging to the subgenus Scapuscutala, and perhaps also related to certain Eutrombicula.

In the same manner Microtrombicula sg. is divided into two groups:

r) gr. verrucascuta: with flagelliform sensillae;

2) gr. minutissima: with bifurcate, trifurcate or (rarely) branched sensilla.

a. Scutum.

The shape of the scutum is important; also the presence of eyes.

1) Traubiella: (Pl. A, 5) typical "eltonella" scutum, clearly punctate, AM fairly longer than ALs and PLs. Eyes present.

2) Coecicula: (Pl. B & HH) scutum pentagonal, with trifurcate sensillae. Eyes absent.

3) Eltonella: (Pl. C-Z & AA-HH) scutum more or less pentagonal, with barbed sensillae. Eyes present.

4) Marcandrea: (Pl. B) scutum trapezoidal, no caudal backward position of the sensillary base lines. Eyes absent.

5) Microtrombicula: (Pl. JJ-ZZ & AB-AS) small scutum subpentagonal, typically verrucose or reticulated. Eyes present.

6) Scapuscutala: (Pl. FF-KK) punctate scutum shaped like those of Eltonella. Eyes present.

The five hairs or barbed setae (1AM, 2AL and 2PL) inserted on the scutum, are also of certain importance, the following length ratio is current: PL>AM>AL or AM>PL>AL; exceptions being: AL>PL (for Eltonella gerrhosauri, Scapuscutala maura and S. meridialis).

The sensillae may be branched, furcated or flagelliform. Flagelliform sensilla is the rule in the verrucascuta-gr; bifurcated sensilla is the rule in the minutissima-gr; but certain sensillae are trifurcated, such as in katangae, bukamae, nasalis and paralumsdeni, or branched as in ornata and wrenni. Too, the apparently bare sensilla stalk is often clothed with some very short and thin barbs.

The scutal surface, as already said, may be punctate or verruco-punctate. The punctuation may be sparsely scattered or dense, the pits constituting that punctuation may be large or very small in diameter. When they are large and numerous, their joining gives to the scutal surface a verrucose or reticulated appearance. This is a peculiarity of most of the species belonging to the Microtrombicula subgenus. The reticulation is much reduced in hexasternalis and non-existant in armata and merrihewi. The punctuations of Traubiella are large; those of Coecicula and Marcandrea are small and very numerous; while Eltonella exhibits
a much more scattered pattern. In the *Eltonella* sg., the *gerrhosauri*-group has a very meager punctuation.

b. *Gnathosoma*.

Its general appearance is close to the normal gnathosoma of most of the *Trombiculidae*. The palpo-tarsal gross formula is uniformly : $fT = 6B$. The palpotibial claw remains a fundamental character depending on the number of its terminal prongs : 2 or 3. Nevertheless, the rule, which entails two-pronged palpal claws for the *Microtrombicula* and three-pronged claws for *Eltonella*, is not always present. For example, *Microtrombicula major*, a typical *Microtrombicula* of the *verrucascuta* group, possesses three-pronged claws instead of two-pronged. Illustrating the contrary case : *fieldi, maura* and *meridialis* are much closer to *Eltonella*, being related to Lawrence’s *gerrhosauri* group, than *Microtrombicula*, in spite of their two-pronged palpal claws. Therefore, their systematic position in the subgenus *Scapuscutala* may be considered only as a provisional one.

In certain cases, the palpal claws are stronger than is usual; *M. (M.) merrihewi* is an impressive example, *M. intranasalis*, a more recent discovery, is another.

The two galeal setae are generally bare, but are branched in four *Scapuscutala* : *crosleyi, maura, meridialis* and *villiersi*.

The palpo-tarsal gross formula, as already stated, is $fT = 6B$. In the past, some ‘ $fT$ ’ were designated as $5B.S$, but that ‘ S ’, which is a nude seta, is not a true “ *Subterminala* ”. In fact the nude setae, sometimes present on the palpal tarsus, are usually hairs deprived of barbs. One way to designate them in the formula could be : $fT = 5B.N$, or $4B.2N$, or $3B.3N...$ but this would lead to confusion, and is not recommended. Also it is better to consider those bare hairs as barbed, because of the similarity of their origin. The phenomenon of barb reduction on the palpo-tarsal setae accompanies a similar reduction of barbs on the dorsal leg setae (pseudomastifemoralae, pseudo-mastigenualae, pseudo-mastitibialae and pseudo-mastitarsalae).

The palpal setulation formula is as follows :

1) *Chiroptella* : (N)-(N)-(N).N.N.

2) *Traubiella* : (B)-(B)-(N).N.B.

3) *Coecicula* : (B)-(B)-(N).N.B or (B)-(B)-(N).B.B.

4) *Eltonella* : (B)-(B)-(N).N.B or (B)-(B)-(B).B.B with any combination of these two formulae : *eltoni* gr. and *rossi* gr.

5) *Marcandrea* : (B)-(B)-(B).B.B.

6) *Microtrombicula* and *Scapuscutala* : any kind of combination of N and B setae. The chelicera ordinarily has a strong base and a well-developed blade. The blade is provided with the usual tricuspid cap and subterminal butting-tooth which may, at times, be modified into a true tooth or hook, as in : *armata, irran-giensis, merrihewi, tamisci* and *paraxeri*. 
c. Legs.

The sternal hair formula is commonly: \( f_{St} = 2.2 \).\(^1\)

But in certain cases, we may find: \( f_{St} = 2.4 \), as in maura and meridialis, or \( f_{St} = 2.2.2 \) as in crossleyi, trisetica and hexasternalis.

The coxal hairs also have a very usual formula \( f_{Cx} = 1.1.1 \), and the three exceptions recorded, are: M. (S) trisetica, \( f_{Cx} = 1.1.3 \), M. (S) rajoriensis, \( f_{Cx} = 1.1.2 \), and M. (S) crossleyi, \( f_{Cx} = 1.1.5 \) (Sometimes 4 or 6).

Coxal and sternal setae always display the same pattern or appearance, a fact that only a common origin can explain; they are definitely different from the other body setae. In the subgenus Microtrombicula, they assume — because of their diversity — taxonomic importance.

Sometimes, the coxal and sternal formulae are done as follows:

\[ f_{Cx} = B_4 . N . B_3 \text{ and } f_{St} = 2N^* . 2N \]

It denotes that the anterior coxal setae is provided with four long branches, the middle coxal hair is nude, and the third has five long branches, that the two anterior sternal hairs are nude but possess two or three short basal barbs (sometimes barely visible!), while the posterior sternal setae are completely bare.

**Trochanter**: this typically curved segment bears always a single fairly long hair, which is usually barbed, sometimes even plumose, or rarely nude as in resseleri (Pl. AC).

**Femur**: This segment is nearly always divided into two articles: basi-and telo-femur. But in certain species we may find undivided or partially divided (semi-division) femurs; this lack of division does not affect necessarily the femur of each pair of legs.

As a consequence, the leg segmentation formula, while \( f_{sp} = 7.7.7 \) for all the Eltonella and Scapuscutala, may show different combinations for many Microtrombicula: \( f_{sp} = \) from 6.6.6 to 7.7.7; (passing through all the possible combinations, including 6!6!6! (in which 6! means a semi-divided femur.)

As is well known, each leg bears a certain number of special setae or ‘organels’ all located on the dorsal surface of the various segments. Only the ‘Pretarsalae ’ 1 and 2 (PT’ and PT”) are located on the ventro-external edge of the first and second tarsi, near the small pretarsus supporting the two claws and the median empodium. At quite an opposite position (dorso-internal curve of tarsus 1) is found the strong and straight pointed ‘Subterminala ’ and its small companion, the slender ‘Parasubterminala ’: ST and \( \rho_{ST} \).

The presence or absence of the pretarsala, the subterminala, and the parasubterminala is here referred to by the abbreviation followed by the sign + or —.

\(^1\) The coxae constitute part of the legs, their setae are sometimes very peculiar. Considering the fact that sternal setae always follow the coxal hairs in their peculiarities, it seems logical to place them under the same common study title: Legs.
For an example, the four species *nasalis, merrihewi, ornata* and *wrenni* would show: $PT' = +$, $PT'' = -$, $ST = +$ and $pST = +$. They are the only known species having no pretarsala.

**Genu :** Leg 1 : generally we find two or three genualae and a small microspur (Famulus). For certain species the genuala number constitutes a true taxonomic character. But for some other species this is not the case and moreover there is a definite inconsistency in the character with, at times on the same specimen, one genu having 2 and the other 3 genualae.

Leg 2 : always bears a single genuala, never a microgenuala (Famulus).

Leg 3 : most trombiculid mites have only one genuala 3, but a few of them, are characterized by the presence of two genualae 3 as in *Sasatrombicula, Chiroptella, Traubiella* and *Marcandrea*, (only the last two being of any interest in the present work).

**Tibia :** On leg 1, we find two solenidions, both more or less striated, and a microspur (Famulus).

On leg 2, same kind of solenidion, but no microspur is to be found.

On tibia of leg 3 there is always a single nude tibiala, very similar to genuala 3.

**Tarsus :** On leg 1, is always found a strong straight seta, the 'Subterminala' and its slender companion, the 'Parasubterminala'. On both legs 1 and 2, there is usually a 'Pretarsala' exception made for *merrihewi, nasalis, ornata*, and *wrenni*, where $PT''$ lacks. Finally, one solenidion (= striated spur) is present, preceded (leg 1) or followed (leg 2) by a microspur (Famulus). The tarsala 1 (or solenidion 1) is very long in *Marcandrea* (Pl. B) and also in some *Microtrombicula* parasitizing bats (*nycteris irangiensis*). In certain species, the apex of the solenidion 2 may be somewhat inflated (*gerrhosauri, maura, meridialis, pachydaactyla* and *audyi*). *Eltonella* sg. and *Microtrombicula* g. always have one mastitarsala on leg 3; *Traubiella, Coecicula* and *Marcandrea* never do.

**Claws :** (and claw-like empodium), always present at the end of each leg, never show any important differences in their morphology.

**Leg Index :** As we have known for a long time, it shows little to express the size of a chigger-mite in terms of its body-length and width. First because, usually the third dimension (body-height) is not taken. In such a case, the dimensions do not mean very much. Furthermore, it is well known that the tendency of the body is to swell up continuously, so that its three dimensions are inconstant and consequently, totally valueless. It seems much more objective to express the relative size of a trombiculid in terms of its leg lengths. Since the legs are almost completely sclerotized, the measurement of their lengths gives a much more constant figure. This led us to sum up the lengths of the three legs to give a single number, easier to remember, more intuitive and expressive, and useful for quick comparison.

Applying that principal:
1) *Traubiella*: 1240 μ, large sized mites.

2) *Coecicula*: 580 to 750 μ, small to medium sized mites, the mean showing a rather small size.

3) *Eltonella*: 540 to 900 μ, small to medium sized mites, but most being between 600 and 700 μ; small size.

4) *Marcandrea*: 620 to 720 μ, small size.

5) *Microtrombicula*: 430 to 880 μ, very small to medium sized, the average being rather small.

6) *Scapuscutala*: 480 to 1010, very small to medium sized (extreme limit).

As a general conclusion, *Eltonella* and *Microtrombicula*, are almost always small mites.

d. *Body or Idiosoma.*

The body shape, in itself, is of real importance in systematics as a rough naked-eye diagnosis, as are the body’s yellowish to orange color and its two reddish eye-spots. By using a good stereoscopic magnifier with properly balanced light, one is able to recognize the more or less hairy nature of the idiosoma and the appearance of the scutum, its setae and sensillae (expanded or not). This on a living mite (*in situ*) on its preanesthetized host. This method, requiring a short training period, is of great importance in ecological studies.

The body setation is of capital taxonomical importance, in regard to the appearance of the various setae, their number and their arrangement on the body (NDV, fD, fV). Also important is the relative position of the anal pore or “uro-pore” (u). In the subgenus *Microtrombicula*, more than in other subgenera, the appearance of the humeral (H), dorsal (D), pygidial (P), ventral (V), coxal (Cx or C), sternal (St or S), and scutal setae (AM, AL, PL) have an exceptional importance. Especially the coxal and sternal setae, which range from nude through a more or less branched appearance (see c. *Legs*), to coarsely barbed.

B. — *Nymph.*

All of those nymphs have in common the palpo-tarsal gross formula:

\[ fT_n = 9B.3S \]

which corresponds to the larval formula: \( fT_1 = 6B \).

The other characters are classical, so their study will be treated individually.

C. — Ecological considerations.

1) Location: Most of the species of the two genera *Eltonella* and *Microtrombicula* appear to be tropical or subtropical mites, as shown in the following list (Loc).

2) Host: The preferred hosts are rodents, but a large number of the subgenus *Microtrombicula* and the subgenus *Traubiella* are bat parasites. Some old world tropical *Eltonella* are purely reptile parasites, while in Equatorial Africa they are mammal parasites. The Central African *Coeecicula* were found on rodents, whereas the American members of that subgenus were found on bats. Very few of the two genera — about ten species — feed on birds. One *Marcanandra* and one *Eltonella* s. str. are recorded from arthropods. Finally, one species, *E. celiae*, was found free-living as a termitary dweller in the company of an adult trombiculid to be described under the name of *Tenotrombicula minteri* (87).

3) Parasitope: The parasitic location of most of the *Eltonella* is the ears of their host. Many other are found on the skin (never in the skin), on the belly, in the groin, or in the armpit; rarely are they found on the eyelid or on the snout.

Members of the genus *Microtrombicula* are also typical ear-dwellers, very often aggregated in large colonies in a very restricted area. Some *Microtrombicula* of recent discovery were found in the nasal passage of mammals: *intransalis*, *nasalis* and *wrenni*, the former from Central Africa, the other two from the U.S.A.

D — List of species belonging to the genera *ELTONELLA* and *MICROTROMBICULA*; and of the subgenus *CHIROPTELLA* transferred to the genus *LEPTOTROMBIDIUM*.

I. — *Leptotrombidium* Nagayo et al., 1916; genus, p. 50.

*Chiroptella* V.-G., 1960; subgenus comb. nov. (type: *insolli* Phil. & Tr., 1950), p. 50.

Abbreviations:

Tr. = Trombicula, Mtr. = Microtrombicula, Elt. = Eltonella, Chir. = Chiroptella,
Coec. = Coecicula, Eutr. = Eutrombicula, Neotr. = Neotrombicula, Marc. = Marcandrea,

D, U, S (first col.) = after the original Description, after Unpublished study, after Study.

Loc. (Zoogeograph. location): At = Australian tropical; Ec, Ee, Es, Ew = Ethiopian:
central, east, south, west; Nc = Nearctic central; NTc = Neotropical central;
Oi, Om = Oriental indian, malaysian; Pm, Ps = Palearctic mediterranian, siberian;
S = Sonoran.

Host: M = Mammal; Mr = Mammal, rodent; Mch = Mammal, chiroptera;
B = Bird; H = Reptile or Batrachian; A = Arthropod; fr = free living on earth.

(N.B.: The plates are lettered from A to Z, from AA to ZZ and from AB to AY).

ADDENDA.

After this revision was completed, I had the opportunity to study the following species, which I now
realize should have been included.

I. — Leptotrombidium Nagayo et al., 1916; genus, p. 50.

A — Chiroptella V.-G., 1960; subgenus comb. nov. (type: insolli Phil. & Tr., 1950, p. 50.

1' giga, Tr.; Schluger et al., 1959
D    Ps    Mch
2' niehoffi, Tr.; Domrow, 1962
D    Om    Mch

D — Eltonella Audy, 1956; subgenus (type: eltoni Audy, p. 58.

27' merga, Tr.; Brennan & Jones, 1960
S    Ntc    B
41' shannoni, Tr.; Ewing, 1929
S    Ntc    M, Mch
44' sternalis, Tr.; Brennan & Jones, 1961
S    Ntc    Mr

A — Microtrombicula Ewing, 1950; subgenus (type: minutissima Oudemans, 1910), p. 84.

19' kyongkiensis, Mtr.; Ah, 1964
D    Ps    Mch
20' loomisi, Mtr.; Ah, 1964
S    Ps    Mch
24' minutiori, Mtr.; Ah, 1964
D    Ps    Mch
37' pipistrelli, Mtr.; Ah, 1964
S    Ps    Mch

Some of these species will be more fully described and illustrated in forthcoming issues of Acarologia.
II. — RÉVISION

A. — Acknowledgment.

The present revision, 1) will not follow the alphabetical order of the preceding checklist; rather the species will be studied in such order as to take care of their individual relationships and affinities;

2) will report the essential data of each species, as it appears on our identification cards.

To clarify the second point, an explanatory example is given here for “Larva” and “Nymph” of Microtrombicula verrucascuta n. sp.

I. — Larva:

Microtrombicula (Microtrombicula) verrucascuta n. sp. [grp. T.]. Cl. n° 46.

a — Host: Mr: Lophuromys aquilus, Dasymys bentleyae. 
PT: ears (auditory duct).
Loc.: Bukavu and Mushwere (Rep. of Congo, Kivu Province).
Date: 12 Feb. 1954.
Type material: Holotype in the Musée d'Afrique Centrale, Tervuren (Belgium).

b — Pl. AH and YY, 5, 6 & 7.

c — SIF = 6B.N.2.3111.100 $fPb = (B)-(B)-(N).B_1.B$
ST = +, $pST = +$  PT' = +, PT'' = +
$fsp = 7.6.6$  $fCx = B_4.N.B_3$  $fSt = 2B_4.2B_1$
$fD = 2H + 6.6.6.4.2 = 32$  $fV = 6.4.6.6.6.2.2 = 36$  NDV = 68

(N.B.: All the measurements are expressed in micra for the nymphs as well as for the larvae.)

Obs.: Very small species, differs from kawaensis in having its dorsal setae devoid of insertion shield; from lophuromyia in the nature of its setae (see Cx1, Cx3, and St2); and from both in having only 6 setae on the first dorsal row, instead of 8.

Explanations: The present name of the species is followed by the number in the preceding alphabetical check-list: Cl. n° 46; and — occasionally — by the qualification of type-species of: genus = T, subgenus = Ts, or group = grp.T.

Under the name are the synonyms, if any, and the references.

a — Ecological data including: names of hosts, parasitope or location on host, locality of host, date of capture, location of the type-material.
b — *Illustration records* : (Plates and fig.).

c — *Identification data* : SIF = Synthetic Identification Formula : including the \( fT = 6B \); the nature (bare or branched) of the two galeal setae ; \( Ga = N \); the number of prongs of the two palpo-tibial claws : \( Gr = 2 \); the number of genualae \( r, 2, \) and \( 3 \) and of tibiala \( 3 : ga = 3, gm = r, gp = r \) and \( tp = r \); finally the number of mastitarsale, mastitibialae, and mastifemoralae \( 3 : MT = r, Mt = o, MF = o \).

\( fPp \) = palpal setation formula, indicating the nature, nude or barbed, of the femoral and genual single setae, and of the three tibial setae ; each dash separating two segments, and parenthesis denoting a dorsal position on the palpus.

\( ST, pST, PT' \) \& \( PT'' \) = subterminala, parasubterminala, pretarsala \( r \) and pretarsala \( 2 ; + \) or \( - \) (= present or absent).

These data and the three following \( fsp, fCx \) and \( fSt \), will usually be reported only under generic and subgeneric descriptions.

\( fsp \) = leg segmentation formula (coxae included) ; \( 7 = seven \) segments, femur divided into basi- and telo-femur ; \( 6 = six \) articles, femur undivided ; \( 6! = six \) segments, but femur only partly divided (semi-division).

\( fCx \) \& \( fSt \) = coxal and sternal setation formulae ; B subtended by a number indicates a branched seta with that number of long branches, \( N = nude, N' \) or \( N'' = nude, \) but having sometimes \( r \) to \( 3 \) barely perceptible basal barbs.

\( fD \) \& \( fV \) = dorsal and ventral body setae formulae ; \( u \) indicates the uropore location.

\( NDV \) = total number of body setae.

Then follow the measurements in micra for which the abbreviations currently known are : \( pa, pm \) \& \( pp \) = lengths of anterior, median, and posterior legs ; \( Ip \) = leg-index, or sum of the three preceding lengths.

*Obs.* : Short record concerning characters having some importance in the differential diagnosis.

II. — *Nymph* :

*Microtrombicula (Microtrombicula) verrucascuta* n. sp.

a — *Host* : *Lophuromys aquilus*.

Loc. : Bukavu.

Larval Date : 12 Feb. 1954.
Emerg. Date : 24 and 25 Feb. 1954 (pupation period : \( 11 \) to \( 12 \) days).

b — Pl. AI, 1 \& 2.

c — \( fTn = 9B.3S \)  ASL/SB = 1,8  PGC : 2  PGS : 1  Hyp \( \times 4N \)

\( fSt = 4B \) to \( 6B \)  Sens : \( SP = 53 \) (short thin barbs), \( SA = 55 \) (16B, of 13 \( \mu \)).
CL = 35  CA = 18  BL = 88  BH = 32  pCS = 9 to 12 (on each side of the Crista).

<td>153</td>
</tr>
</tbody>
</table>

Obs. : Very small species.

Explanations:

a — Name and ecological data as for the larva. Emerg. Date = date of emergence of the young nymph, after its period of pupation, starting with the larva date.

b — Illustration records.

c — Identification data : still very poor for nymphs.

fTn = palpo-tarsal gross formula using the signs similar to those of the larva : 9B.3S (corresponds to a larva having a fT = 6B.) The ratio ASL/SB may at times prove very useful from a taxonomic view point.

PGC & PGS = paraglyphic ctenidia (comb) or spines and paraglypic seta; the former dorsal and generally two in number, the latter ventral and usually single, straight, long and nude.

Hyp. = the two apical lobes of the hypostome, each bearing nude setae generally four in number.

fSt = number of setae on the sternal shield.

Sens. = sensilla : SP = length of its pedunculate basal part, and SA = the length of its apical branched part. SP = 53 and SA = 55 (SA bears 16 slender branches being about 13 μ each.)

CL and CA = Cheliceral blade length and articulation height.

BL and BH = Length and Height of the chelobase.

pCS = paracristal setae, 7 to 10, on each side of the crista-metopica.

Then follow the standard measurements:

ASL, PSL, and CTL = distance from tectal-seta base to sensillary base line, from sensillary base line to the end of the posterior sclerite, and total length of the crista-metopica (from the anterior edge of the tectal denticulate fringe to the pointed end of the posterior sclerite).

S & SB = length of the sensilla and distance between the two sensillary bases.

T = length of the tectal barbed seta.

IL = body length.

PW, OW, CW = propodosoma, opisthosoma, and constriction width.

P₁, P₂, P₃ & P₄ = length of the four legs (coxae included, claws excluded).

IPn = leg-index, sum of the four leg lengths.

D = length of the dorsal hairs, on propodosoma and caudal edge.
TL, TH and tL = first leg-tarsus length and height, and first leg-tibia length.
N. B. : The plates AC to AS date from 1955!

B. — Description.

I. — Genus *Leptotrombidium* Nagayo et al., 1916.
Subgenus *Chiroptella* V.-G., 1960, n. comb.

= *Eltonella (Chiroptella)* V.-G., 1960 (75) in part.

= Eutrombicula (Squamicola) Audy & V.-G. 1961 (17).
= Eltonella (Eltonella), V.-G., 1960 (75).

LARVA:

a — Hosts : A, B, H, M, Mr, Mch and fr.
PT: surface of skin (never in the skin), generally in the ears of B and M.
Loc: in tropical or subtropical, and equatorial regions, all over the world.
Subgenerotype: Eutrombicula (Eltonella) eltoni Audy, 1956.

b — Pl. C to Z, AA to FF & HH.

c — SIF = 6B.N.\(3^2\)31111.000  
\[ f/P" = (B)-(B)-(R). N. B. B, also \]
\[ f/S = 7.7.7 \]
\[ f/Cx = B.B.B \]
\[ f/ST = 2B.2B \]
Ip = 540 to 900.

Obs. : Sub-pentagonal punctate scutum, with branched sensillae; paired eyes, only one genuala, one tibiala and one mastitarsala on leg 3; the two galeal setae always nude.

NYMPH:

\[ f/Tn = 9B.3S \]
\[ ASL/SD = 2.4 \]
\[ PGC = 2 \]
\[ PGS = 1 \]
\[ Hyp. = 2(4N) \]
\[ f/St = 4 \]

Sens: filamentous. Eyes absent (exceptionally, present in eltoni)
IPn = 900 to 2 000.    pCS = 3 to 10

1. Eltonella (Eltonella) eltoni, (Audy, 1956) [T] [Ts] [grp. T.] Cl. n° 21.

= Eutrombicula (Eltonella) eltoni, Audy, 1956 (11), Womersley & Audy, 1957 (85).
= Eltonella (Eltonella) eltoni, V.-G., 1960 (75).
= Trombicula (Tragardhula ?) sp. indet., Audy, 1950 (6).
= Trombicula (Trombicula) fritssi, Womersley, 1952 (in part.) (84).
= Trombicula (? ilesi-grp) fritssi, Audy, 1954 (in part.) (9).
LARVA:

a — Host: A: Heterometrus longimanus (Giant black scorpion) — R. 7971.
PT: inter-segmental joints.
Loc.: Bukit Lagong Forest Reserve, Kepong, Selangor, Malaya: Om.
Date: 21 September 1949.

b — Pl. C, 1 to 5.

c — SIF = 6B.N.3.3111.000  j/P^p = (B)-(B)-(B).B.B
jD = 2H + 6.6.4.2.2 = 22  j/V = 18  NDV = 22 + 18 = 40.

Obs.: The only member of subgenus Eltonella which is parasitic on arthropods, and which lacks a mastitarsala 3, by exception.

NYMPH:

a — Host: A: Heterometrus longimanus — larval stage host.
Larval date: 21 September 1949.
Emerg. date: 10 to 14 October. 1949; pupation period: 19 to 23 days.
Type material: Nymph-Type (BM.1956.8.21) at the British Museum, London.

b — Pl. AT, 1, 2, 3, 4.

c — j/Tr = 9B.3S  ASL/SB = 2.4  PGC = 2  PGS = 1
Hy = 2(4N)  j/St = 5 or 6 B.
Sens: SF = 25 (short barbs), SA = 45 × 3 (breadth) (numerous barbs).
Eyes present.
CL = 32  CA = 16  BL = 57  BH = 21  pCS = 2 or 3 (on each side of the crista).

Obs.: Very small species; exceptionally oculete, like some Eutrombicula.

a — Host: Procavia sp.
PT: ?
Loc.: Kaabong, Uganda, B.E.Af.: Ee.
Date: 26 Apr. 1952 (and 33 specimens, received later: 21 Sep. 1955; same loc.)
Type material: at the Rocky Mountain Laboratory; Holotype: n° 26452/P/1 (RML: 31469).

b — Pl. C, 6 to 10.

c — SIF = 6B.N.3.3111.100
fPp = (B)-(B)-(B).N.B
fCx = B.N'B
fSt = 2B.2N'

Obs.: Scutum rather similar to that of abyssinica; the scutal setation is different and there are two genualae on leg I instead of three.

= Eltonella (Eltonella) ugandae felis n. ssp.

Note: Three other variations of E. ugandae will be studied hereafter, under the three following distinctive signs: Ot/B, Oh/S, Pj/S.

a. Eltonella (Eltonella) ugandae ugandae

Larva:

a — Hosts: M: Canis familiaris; B: Centropus grilli.

PT: eyelid of dog, skin of neck and belly of bird.

Loc.: Entebbe, Uganda, B.E. Afr. (dog); Luvungi, Ruzizi Valley, Rep. of Congo: Ee and Ec.

Date: June 11, 1952 (dog); 23 May 1954 (bird).

Type material: Holotype in the Musée d’Afrique Centrale, Tervuren (Belgium).

b — Pl. L, 1 to 4.

c — SIF = 6B.N.393 N.III.1100 /Pp = (B)-(B)-(B).N.B /Cx = B.B.B

/ST = 2B.2B /D = 2H + 10.8.8.4.4.2 = 38

/V = 6.4.4.6.6.6.4.4.2 = 38 NDV = 76.

Obs.: Differs from the other subspecies in its measurements and in the appearance of its scutum.

Nymph:

a — Host: Centropus grilli.

Larval Date: 23 May 1954.

Emerg. date: 14 June 1954; pupation period: 22 days.

Type material: Nymph-type in the Musée d’Afrique Centrale, Tervuren (Belgium).

b — Pl. L, 5 and N, 3, 4.

Obs. : Smaller than ssp. ugandae ; rachis of the body setae more slender.

Observations on the species ugandae and polymorpha :

1) E. ugandae and E. polymorpha are two closely related species ; the four
major differences are : a) posterior scutal edge more sharply pointed in polymorpha ; b) first dorsal row of setae having 10 setae in ugandae, 8 in polymorpha ; c) solenidion r and 2 smaller in polymorpha ; d) mastitarsala 3 in proximal position for ugandae with respect to the two nearest plumose setae.

2) The species ugandae is of particular interest due to the individual instability of one very peculiar and important taxonomic character : the number of ga (or genualae r). This number sometimes varies on specimens belonging to the same population, indicating an actual instability of the character. For the three variations : Ot/B, Oh/S and Pf/S, the number is invariably 2ga on the first pair of legs. In contrast, in ugandae and felis, the number is usually 3ga, with only two exceptions seen in each subspecies. It is to be noted that the number of ga is always 3 for the species polymorpha.

**Obs.** : Differs from ssp. *yangi* in its *ga* = 3, in its palpal formula (*fPp*), and in its body setation formulae. There are, besides, some more observations made on 42 specimens:

1) The *ga* is ordinarily 3, but one may also find on one side *ga* = 2 at the rate of 3.56 %, which is quite minor.

2) The leg measurements show the following extremes:

<table>
<thead>
<tr>
<th></th>
<th>195</th>
<th>163</th>
<th>190</th>
<th>548</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>

PT : ears.
Loc. : Astrida, Rwanda-Burundi, Africa : Ee.
Date : 31 Jan. 1952.
Type material : Holotype in the Musée d’Afrique Centrale, Tervuren (Belgium).

b — Pl. T, 1, 2, 3, 4, 5.
c — SIF = 6B.N.3.2111.100 /Pp = (B)-(B)-(B).N.B /Cx = B.B.B
fSt = 2B.2B /D = 2H + 8.8.6.4.2 = 30 /V = 6.6.6.6.2 = 26
NDV = 30 + 26 = 56.

Obs. : Differs from any other species in its dimensions and body setation.

25. Eltonella (Eltonella) celiae n. sp. 1. Cl. n° 18.

Note : As already observed on other occasions and noticed by several authors, the coexistence of two forms in the same population of chigger mites is a very con-

1. This species is named after Mrs. Celia Minter, at the request of her husband Dr. D. Minter, to whom I intended dedicating this species before. Dr. MINTER, Medical Entomologist of the Medical Research Laboratory of Nairobi (Kenya, British East Africa) has sent us, in the past, numerous remarkable collections. We are greatly indebted to him for his disinterested collaboration, and for enabling us to share in his gallant gesture.
tradictory feature. In the case of *E. celiae* one is able to separate the free-living mites in two definite lots: one consisting of large specimens, the other composed of small representatives. In this work the large mites will constitute the type material of *E. celiae*, the smaller ones will be considered as a variation and designated as *E. celiae* " M ".

a. *Eltonella (Eltonella) celiae* n. sp.

a — Host: fr: the larvae were found: " ... swarming at the tops of the ventilation shafts of the mounds of *Macrotermes bellicosus* Smeath., both inside and, outside the shaft, but only over the apical few inches of the shaft. The mites exhibit the phenomenon of ' clustering ' on high points of the micro-habitat. Do not attempt to bite man apparently. Colour: Dull white, with red eyespots." ... after Dr. D. MINTER (in litt., 1956).

Date: 1 May 1956 (again on 24 May 1956).

Type material: Holotype in the Musée d'Afrique Centrale, Tervuren (Belgium).

b — Pl. U, 4, 5, 6 & V, 4, 5, 6.

c — SIF = 6B.N.3.3III.100  \( jPp = (B)-(B)-(B).N.B \)  \( jCx = B.B.B \)

\( fSt = 2B.2B \)

\( fD = 2H + (4.6).6.6.6(2.8).8.4.2 = 54 \)

\( fV = (2.6).6.6.6,6.6.6.4 = 48 \)

NDV = 102.

**Obs.**: Very close to the form " M ", but larger in size. Some variation occurs in the number of branches on the palpal setae; sometimes the \( fPp \) may be different from one palpus to the other on the same specimen. The observed \( fPp \)'s are comprised in the two formulae:

\[ fPp = (B)-(B_2)-(B_3).N.B_1, \]  \( fPp = (B)- (B_2)-(B_3).N.B_3. \)

The setae \( Cx_1, Cx_2, \) and \( St_1 \) are distinctly branched (4 to 6 branches) but \( Cx_2 \) and \( St_2 \) are definitely barbed (Pl. U, 4 — \( Cx_m, Cx_p, \& St_a, St_p \)).

On rare occasions the galeal setae may bear a thin branch, always unilateral on the observed material (13 B_1 for 87 N).

Variations were also found in the number of accessory prongs on the palpal claws, using 19 specimens. Usually these variations are unilateral:

\( G_1-G_3 : 1, \)  \( G_3-G_3 : 10, \)  \( G_3-G_2 : 2, \)  \( G_3-G_2 : 6, \)  \( G_3-G_2 : 6, \)  \( G_2-G_2 : 2. \)

The measurements show very few variations; for example, the \( Ip \) varies only between 846 and 888, i.e., \( \pm 2.45. \)

b. *Eltonella (Eltonella) celiae* " M ", (variation).

a — Host: fr: free in the same biotope as that of the previous large form (and in its close company).

Loc.: see *celiae*. 
Date: same as celiae.
Type material: Holotype in the Musée d’Afrique Centrale, Tervuren (Belgium).

b — Pl. U, I, 2, 3 and V, I, 2, 3.
c — SIF = 6B.N.3.3111.100 /Pp = (B)-(B2)-(B1).N.B1 /Cx = B.B.B
   /St = 2B.2B /D = 2H + (4.4).6.6.6.6.4.4 = 46
   /V = (2.6).6.6.6.6.4 = 48  NDV = 94.

Obs.: Size smaller in comparison to celiae s. str. The caudal setae of both forms are thickened; those of “M” are thicker and shorter (Pl. V, 1 and 4 D). Also there is a marked difference in the solenidions of leg-tarsus 2, and in the relative position of the microspurs (famuli) of leg-tarsus 1 (Pl. V, 2, 3 and 5, 6). Finally, there are definite differences in the scuta of the two forms.

Peculiar consideration: E. celiae was captured in the same vicinity as an adult described under the name of Tenotrombicula minteri n. g., n. sp., V.-G. (87). It is quite possible that this adult is the parent of the chigger-mite celiae. In that case, this would be an interesting example of morphological divergence of adults due to an ecological influence (as termitarium dweller). It is to be noted that the characters of T. minteri could fit in with those of a mite having a fT = 6B, and belonging to the genus Eltonella.

26. Eltonella (Eltonella) buxtoni (Womersley, 1952). Cl. no 16.

= Trombicula buxtoni Womersley, 1952 (84), Radford 1954 (64).
= Trombicula (Trombicula) buxtoni, Audy, 1954 (9).
= Trombicula (Miyatrombicula) buxtoni, Womersley & Audy, 1957 (85).

Note: Womersley and Audy (1957) erroneously placed this species in Miyatrombicula only on account of its scutal shape and its bisetose coxa 3.

a — Host: Mr: “yellow rat”?

Obs.: Microtrombicula of small size with typical subpentagonal scutum, small and verrucopunctate; sensilla simple, bi- or tri-branched; galeal setae bare; palpal claw bifurcate; oculate.

NYMPH:

a — Pupation period: 18 to 28 days.
b — Pl. AI, AK, AS, AT, AU.
c — fTn = 9B.3S ASL/SB = 1.8 to 2.8 PGC: 2 PGS: 1
Hyp.: 2 (4N).
Sens.: slender or slightly expanded, branched or barbed. fSt = 4 to 10 B.

Obs.: Body eight-shaped; appendages normally developed: IPn = 1000 to 1800.
Idiosome whitish, no eye-spots.

Note: The subgenus Microtrombicula can be divided in two "groups":

(a) MINUTISSIMA-GROUP: with bi-furcate or bi-branched sensillae; or, with these exceptions to the rule, M. katangae, M. bukamae and M. nycteris having tri-furcate or tri-branched sensillae.

(b) VERRUCAASCUTA-GROUP: having simple whiplike sensillae. Generally the base, or peduncle, of the sensilla is covered with short and tiny barbs, or spicules.

On the bifurcate sensilla the splitting in two equal branches occurs at the half-length of the organel. On the tri-furcate sensilla, the proximal branch appears at the half-length also and is about a third the length of the main branch. The distal branch is born about half way between the proximal branch and the tip of the main branch, and its length is slightly less than that of the main branch.

The leg-tarsi also show an interesting character:

1) Leg-tarsus 1 always possesses a proximal internal ring of thickened scleroprotein commonly called "bar" (b); in almost all the Microtrombicula, one is able to observe
the existence of one, or two, half-rings or semi-bars (sb) reinforcing the ventral wall of the tarsus;

2) Leg-tarsus 2 has the same armature but only one semi-bar;

3) Leg-tarsus 3 is rarely provided with an extra-bar or semi-bar.

In conclusion one may write the "leg-tarsi bar formula" as follows:

\[ f_{BT} = (b)(2sb) - (b)(sb) - (b)(sb) \] as a maximum case,

\[ f_{BT} = (b)(sb) - (b) - (b) \] as a minimum case.

Chigger-mites preserved in alcohol for a long time, or "hyper-clarified" in lactophenol, are more difficult to be checked concerning their f/BT. This is probably a reason that many authors never refer to that interesting taxonomic character.

Studied :

n° 24972 ..................  46  45  28/26  22/28  212  176  212  600

Obs. : The famulus 2 (microtarsala 2) is situated, unusually, in front of the sole-nidion (striated spur). The setae are slender and their apices end imperceptibly; but this is the case in a great number of Microtrombicula. The papal claws are long and slender also, and the chelicerae possess a dorso-subterminal butting process. The two humeral setae are fairly long (see Pl. PP, i5 H).

23. Microtrombicula (Microtrombicula) paralumsdeni n. sp. Cl. n° 34.

= Eutrombicula lumsdeni RADFORD, 1953 (63) in part.

Notes: Eutrombicula lumsdeni, as described by RADFORD, is rather different from the specimen described presently and which he sent to me as a paratype of E. lumsdeni.

a — Host: M: Procavia abyssinica meneliki.
   PT: ?
   Date: 1952.
   Type material: Holotype in the Musée d'Afrique Centrale, Tervuren (Belgium).

b — Pl. RR, 1 to 5.

c — SIF = 6B.N.2.311.100 /Pp = (B)-(B)-(B).B.B /Cx = B₂.N.B₃

/St = 2N*:2N* /s/ = 7.666! /D = 2H + 6.6.6.4.4.2 = 38

/V = 6.8.6.6.8.4.4 = 42 NDV = 80.

Obs.: After M. nycteris, this species is the largest in the minutissima-group (Ip 640), also its scutum covers a surface nearly as extensive as the scutum of M. major (Pl. AB, 7). The body setae are covered with tiny, slender barbs. The dorsal setae of the legs are slender and possess only rare and tiny barbs; these setae are very similar to the homologue, with curling tips, in M. hexasternalis. The sensillae are tri-furcate as in M. katangae and M. bukamae.

= Trombicula nycteris Jadin, V.-G. & Fain, 1955 (44), Taufflieb & Mouchet, 1959 (70).

a — Host: Mch: Nycteris macrotis.
   PT: ears.
   Loc.: Nyumba caves, Nyanza (nr. Astrida), Rwanda-Burundi, Africa: Ee.
   Date: 13 Nov. 1955 (coll. Dr. A. Fain).
   Type material: Holotype in the Musée d'Afrique Centrale, Tervuren (Belgium).

b — Pl. QQ, 6 to 10.
Obs. : Differs from any other species of the minutissima-group in its bare palpofemoral setae and its $fP_p$. On 76 specimens, two sensillae are trifurcate, all the others having two branches. The leg-tarsi 1 and 2 have strong and fairly long solenidions.

(b) verrucascuta-group, V.-G. & Audy, 1956 (77).

This group is characterised by having undivided, simple and whiplike sensillae. Almost all have the proximal half of their sensillae covered with tiny, nearly imperceptible barbs. *M. nasalis*, *M. wrenni* and *M. ornata* possess fine branches on the distal half of their sensillae.

The largest species: *M. major* (Ip 864) has, unusually, trifurcate palpal-claws. *M. merrihewii* and *M. armata* are the only two species with punctate instead of verrucose scuta.

Eight species are bat parasites, and three of these are intranasal: *M. nasalis*, *M. wrenni* and *M. intranasalis*; but *M. irangiensis*, studied here for reasons of convenience, belongs to the minutissima-group in having furcate sensillae.

25. Microtrombicula (Microtrombicula) verrucascuta n. sp. [gr. T]. Cl. n° 46.

Obs. : Very similar to *M. kawaensis*, *M. vanhoofi* and *M. verrucascuta*. Differs from the first in having only two genualae 1, no large, circular insertion plates for the dorsal setae, and no mastitarsala 3. From the second in its different pilosity, and in the thinner aspect of its leg-tarsus solenidions 1 and 2. From the last one in its general measurements, its setation in general, and the exceptional absence of nude mastitarsala 3.

37. *Microtrombicula* (*Microtrombicula*) vanhoofi n. sp. 1. Cl. n° 45.

**Larva**:

a — Hosts : Mr : *Praomys* sp., *Oenomys hypoxanthus*, *Rattus rattus alexandrinus*. PT : ears.
Dates : 19 Feb., 27 Feb. and 19 Mar. 1954 (coll. Dr. Pierlot, Mr. Lorgé & Mr. Sadin).
Type material : Holotype n° 19254/C/1 in the Musée d' Afrique Centrale, Tervuren (Belgium).

Obs. : Differs from the preceding species in having 3 genualae on leg 1, another /PP and /ST; from *M. verrucascuta* in having other /PP, /Cx, /ST and /D, and no mastatarsala 3.

**Nymph**:

a — Host : *Praomys* sp.
Loc. : Lwiro.
Larva date : 19 Feb. 1954.

1. This species is respectfully dedicated to the memory of Prof. Dr. VAN HooF, my esteemed master, Chief-Physician in the Belgian Congo and Director of the Institute of Tropical Medicine of ANVERS (Belgium).
Emerg. dates: 4, 7, 8, 9, 12 and 15 Mar. 1954; pupation period: 16 to 25 days.
Ref. material: Specimens in the Musée d’Afrique Centrale, Tervuren (Belgium).

b — Pl. AK, 1 to 4.

c — $fTn = 9B.3S$  ASL/SB = 2.1  PGC = 2  PGS = 1
$fSt = 4B$.  $Hyp. = 2 (4N)$
Sens. : $SP = 38$ (apparently nude)  $SA = 66$ (many short branches, 9 $\mu$).
$CL = 46$  $CA = 26$  $BL = 85$  $BH = 37$
$pCS = 8$ to $10$ (on each side of crista).

Obs.: Very small species; differs from $M. verrucascuta$ in its ASL/SB ratio and its sensillae, also in its body setae.

38. Microtrombicula (Microtrombicula) seiurieola n. sp. Cl. n° 41.

a — Host: Mr: *Sciurus* sp.
PT: ears.
Date: 30 Jul. 1957 (coll. Mr. G. Sadin).
Type material: Holotype n° 30757/V/1 in the Musée d’Afrique Centrale, Tervuren (Belgium).

b — Pl. XX, 6 to 10.

c — $SIF = 6B.N.2.3111.000$  $fPp = (B)-(B)-(N).B.B$  $fCx = B.B.B.$
$fSt = B.B.$

Obs.: Very similar to the two preceding species as regards the shape of the scutum, but larger in size. No nude mastitarsala 3. Chelicera with a dorso-subterminal butting tooth. Setae covered abundantly with long barbs (fig. 8).

39. Microtrombicula (Microtrombicula) alexandrina n. sp. Cl. n° 1.

a — Host: Mr: *Rattus rattus alexandrinus*.
PT: ears.
Date: 19 Mar. 1954 (coll. Mr. Lorgé).
Type material: Holotype n° 19354/1 in the Musée d’Afrique Centrale, Tervuren (Belgium).
40. *Microtrombicula (Microtrombicula) oenomyia* n. sp. Cl. n° 31.

**a** — Hosts: Mr: *Oenomys hypoxanthus*, *Rattus rattus frugivorus*, *Claviglis smithi*.
PT: ears.

Dates: 8 Sept. 1953, also 15 & 24 Sept. and 19 Oct. 1953 (coll. Dr. Szpaj-schendler and Mr. J. Wolfs).

Type material: Holotype no 8953/A/1 in the Musée d’Afrique Centrale, Tervuren (Belgium).

**b** — Pl. YY, 13, and AN.

**c** — SIF = 6B.N.2.3III.100  /Pp = (B)-(B)-(B).B.B  /Cx = B.N.B

/Sl = B.B.3  /Sp = 7.6!6  /D = 2H + 6.6.6.6.4.2 = 36

/V = 6.6.2.6.4.4.4  NDV = 68.

Obs.: Very close to *M. oenomyia*, as to the scutal shape and aspect, but the last named has no nude mastitarsala 3.

41. *Microtrombicula (Microtrombicula) becquaerti* n. sp. 1. Cl. n° 5.

*Note*: A certain number of mites were found in the ears of an *Anomalurus jacksoni*, captured by Dr. Christy on February 26, 1913 in Luida (Mawambi-Uélé, Belgian Congo). They were labeled under the name of *T. christyi*. The above sciurid was preserved in alcohol and registered in the Musée d’Afrique Centrale of Tervuren (Belgium) under the no M.C. 16505. The mites collected in 1955 were studied at that time under unsatisfactory conditions, which led us to an improper determination. Recent observations showed that they are definitely not separable from *M. becquaerti*. In the meantime, specimens labeled *T. christyi* were mailed; they have to be considered as *M. (M.) becquaerti*. The figures on Pl. AB are those of the slides labeled as *christyi*.

1. This species is dedicated to the Professor Dr. J. Becquaert, with the expression of my sincere admiration for his scientific work.
a — Hosts : Mr : Paraxerus cepapi quotus, Anomalurus jacksoni.
PT : ears.
Loc. : Elisabethville (Katanga), and Luida (Uélé), Rep. of Congo, Africa : Ec.
Date : 28 May 1912 (E’ville), 26 Feb. 1913 (Uélé) (coll. Dr. J. Becquaert & Dr. Christy).
Type material : Holotype n° 28512/V/2 in the Musée d’Afrique Centrale, Tervuren (Belgium).

b — Pl. YY, 8 to 10, also AB, 3 to 6.

c — SIF = 6B.N.2.3III.100 /Pp = (B)-(B)-(B).B.B /Cx = B4.N.B3

Obs.: This species is close to *M. panieri*, but differs in its pilosity arrangement and in its Ip.

*Otonyssus*, Buitendijk, 1945 (23).

*Eutrombicula*, Lawrence, 1949 (46), Audy, 1956 (11), Taufflieb, 1960 (68).

*Trombicula* (*Trombicula*), Wharton & Fuller, 1952 (82), Audy, 1954 (9), Womersley & Audy, 1957 (85).

*Trombicula* (*Neotrombicula*), Womersley, 1952 (84), in part.

*Trombicula* (*Miyatrombicula*), Womersley & Audy, 1957 (85), in part.

Note: This subgenus lacks indubitable homogeneity. In fact, the analysis of the species included justifies their eventual place in either *Eltonella* or *Microtrombicula sensu stricto*. For instance, the following species belong to a special group of *Eltonella*, the gerrhosauri-group: *fieldi* Audy, 1956, *maura* Taufflieb, 1960, *meridialis* Taufflieb, 1960 and *rhoptropi* Lawrence, 1949. They are parasites of reptiles and Audy and Vercammen-Grandjean (1961) created for them the subgenus *Squamicola*, a name insufficiently supported for the status of subgenus.

In the same way, the following species also belong to a group of mammal parasites more *Eltonella* than *Microtrombicula*: *khurdangensis* Womersley, 1952, *rajo-riensis* Womersley, 1952, *villiersi* n. sp. and *womersleyi* n. sp.
Finally, the following could have been placed under the subgenus Microtrombicula: crossleyi Loomis, 1954, munda Gater, 1932, spicea Gater, 1932 and trisetica Loomis & Crossley, 1953. The case of spicea Gater, 1932 requires special attention by the fact that it possesses two slightly expanded sensillae — just like Ascoschoengastia (Paralaurentella) oenigma (Lawrence, 1949) — and because of that, it constitutes another interesting link bringing close together the two important complexes: Eltonella-Microtrombicula and Ascoschoengastia.

Notwithstanding the preceding considerations, the maintenance of the subgenus Scapuscutala is desirable as a link between Eltonella and Microtrombicula, making evident their very close relationship.

**LARVA:**

a — Hosts: B, H, M, Mr.
PT: ears, body.
Loc.: Tropical, subtropical, and temperate regions; old and new world.
b — Pl. FF to II, and KK.
